5613. LATE SEQUELAE OF CLOSED CEREBROCRANIAL INJURIES AFFECTING THE VISUAL SYSTEM - Neskoré následky zatvorených mozgovolebečných úrazov na zrakový systém - Grodan A. and Šimig I. Chir. Klin. Lek. Fak. Univ. Komenského, Košice.; Očnej Klin. Lek. Fak. Univ. Komenského, Košice. - BRATISL. LEK. LISTY 1959, 39(I)/2 (65-77) Graphs 5 Tables 3

The condition of the optic analysor apparatus was examined in 478 patients with closed cerebrocranial injuries. The field of vision was pathological in 35.56% of 814 cases examined some considerable time after the accident. Colour perimetric findings were pathological in 37.4% of 482 cases tested. Prague, Ceskoslovenska Psychiatrie, Vol 59, No 1, Jan 63; pp 1-[illegible].

Abstract [English summary modified]: Statistical data and [illegible] on [illegible] patients with various types of recent head injuries, [illegible] of these had various psychic difficulties, most frequent being memory lapses ([illegible]) and [illegible] -- obnubilation ([illegible]7). Data from [illegible] returned questionnaires are also tabulated, listing mental-emotional complaints after accident. In most, intellectual functions and memory were affected to varying degrees depending on age, location and severity of injury and other factors. Five diagrams, 5 Soviet, 4 Czech, 1 Hungarian and 17 Western references.

"Determination of the O Antigen in Typhoid Vaccines by Means of the Metachromatic Reaction"

Warsaw, Medycyna Doswiadczalna i Mikrobiologia, Vol 23, No 3, 1966, pp 237-245.

Abstract (Authors' English summary modified): A spectrophotometric method is described for quantitative determination of O antigen in typhoid vaccines. It is based on the metachromatic properties of the antigen, which forms a metachromatic complex with toluidine blue in high ionic strength solutions. Optical density is measured in metachromatic maximum absorption band and in the peak of the free dye. The ratio of the two densities is plotted against the O antigen concentration, and the amount of antigen that binds the dye completely is determined. The method was used for determining the O antigen contents in 4 typhoid vaccines employed in field trials, and the results compared with those of serological determination. Contains 3 Tables, 2 Figures and 11 [illegible] (8 Polish, 8 Western and 1 German-language).

2219. EXPERIMENTAL ERYTHROBLASTOSIS IN RABBITS. I. THE ANTIGENIC STRUCTURE OF RABBIT BLOOD - Doświadczalna erytroblastoza u królików. I. Struktura antygenowa krwi królików - Grodecka U. and Osińska M. Inst. Immunol. i Terap. Dośw. PAN, Wrocław - ARCH. IMMUNOL. TERAP. DOSW. (Wrocław) 1957, 5 (373-385) Tables 10

In order to obtain an experimental model for the haemolytic disease due to the incompatibility of blood groups in mother and child, the authors performed serological studies on rabbits. The serum used for the experiments was that of 5 rabbits which had previously been given the serum of a female rabbit giving birth to dead foetuses and with symptoms of erythroblastosis. Using in turn the serum of these 5 rabbits in the blood examinations of 69 rabbits, the authors found that the above-mentioned sera contained several antibodies directed against one or several antigenic principles. These results will permit the selection of animals, necessary for the proper mating of rabbits to produce experimental erythroblastosis.

TITLE: Radioluminescence of styrenemethylmethacrylate copolymers

SOURCE: Nukleonika, v. 10, no. 8, 1965, 469-476

TOPIC TAGS: radioluminescence, copolymer, styrene, methylmethacrylate, light emission

ABSTRACT: The concentration dependence of the radioluminescence efficiency of solutions of styrene in methylmethacrylate were studied before and after polymerization. Conclusions were drawn indirectly from the measurements of the relative light emission intensity of 2-(1-naphthyl)-5-phenyloxazole, which was added to the solutions as an admixture with unchanged concentration. With dilution of styrene by methylmethacrylate the radioluminescence intensity decreased, thus methylmethacrylate can be considered as absorbing substance causing the quenching of radioluminescence. It was established that the radioluminescence efficiency of solutions of 80% styrene and 20% methylemthacrylate was equal to that of polystyrene solutions. The authors thank Professor V. Mostsitskiy for the valuable advice and interest in this work. Further thanks is extended to I. Kachinskiy for his active assistance in the preparation of the solid solutions. ABSTRACT: The functions and library equipment of this reference and information center are described. Because the work depends on a close cooperation with the scientific technical library, recommendations were made for further improvement of this relationship by a partial mechanization of the procedures through the use of special perforated card-systems (perfo-cards). Cards with marginal perforation which required special hardware in handling were inferior to the visual perfocards manufactured by the computer factories and used without any mechanical equipment. The card systems were classified as thematic- or specialty-registers according to their functions. Visual and marginal perfo-cards were used in both cases. Thematic

Card 1/2

L 30118-65
ACCESSION NR: AT5003806

description cards were written in direct coding for each article in the scientific-technical library (sometimes such cards included the addresses of pertinent industrial organizations). Further improvement in speed and working accuracy was achieved by the introduction of automatic punch-cards processed by 80-column mechanical computers; this system was used for cataloging electrical machinery. The catalog contents were transferred to nonperforated cards size K5; each card was given an order number which was then punched on the corresponding number of the parallel visual perfo-cards (containing descriptions) by a standard 80-column card-punch machine. The visual perfo-cards were written in the same descriptive code developed previously for the marginal card systems. A very practical thematic card file of purely bibliographic nature was introduced. A simple information language containing 57 descriptors was developed for the marginal card system; an annotated bibliography with the descriptions arranged in the numerical order was the information source for the visual card systems. Searching procedure with both systems was simple and required little time. Orig. art. has: 6 figures.

TITLE: Guiding Device for Automatic Welding (Sledyashsheye ustroystvo dlya avtomaticheskoy svarki)

PERIODICAL: Avtomaticheskaya Svarka, 1958, Nr 4, pp 92-94 (USSR)

ABSTRACT: The described device, developed at the Electric Welding Institute imeni Paton, automatically directs electrodes in difficult-to-reach spots, in particular in welding inside seams on large-diameter gas line pipes. Prior to welding, a "bearing line" must be traced on one of the pipe blank edges with the use of a special floating cutter head (Figure 1) which is attached to the end of the top crosshead beam on an edge-finishing mill. The electrical system of the device (shown in Figure 2), comprises a guide block consisting of a bridge with two semi-conductor photo-resistances and an optical system, a phase-sensitive amplifier, an electric machine amplifier, and an electric mechanism switching-in the motor and the reductor. The guide block is mounted on the welding nozzle or on the welding head housing. The image of the "bearing

Card 1/2

Guiding Device for Automatic Welding 125-58-4-14/15

line" falls on the photo-resistances, and when they are lit equally - the bridge is in balance. Even a slight displacement of electrodes from the center line on the blank causes a displacement of the guide block from the "bearing line", which in turn causes a signal and actuates the machine amplifier. The polarity of the signal determines the rotation direction of the motor and hence a displacement of the electrodes back to coincidence with the center line. It was shown in long tests at the Khartsyzskiy trubnyy zavod (Khartsyzsk Pipe Plant) that the displacement of electrodes from the weld center does not exceed 1 mm to one or the other side. The device is reliable and does not require highly-skilled operators It is recommended for use in the production of pipes.
There is 1 photo and 1 figure.

TITLE: The Programming of Welding Processes

PERIODICAL: Avtomaticheskaya svarka, 1959, Nr 10, pp 31-38 (USSR)

ABSTRACT: The article is concerned with programming installations for the automatic regulation of fast and prolonged welding operations, and the author divides the operations into 3 groups. The first one is that for fast welding processes, the program of which is illustrated in Fig 1. The program of the voltage may be arrived at simply and accurately by means of the layout given in Fig 2. The power of the resistances r is selected as being less than r_1, r_2, r_3; the voltage in the resistances r is thus $U'_I = r(i_1 + i_2 + i_3)$ and $U''_I = r(i_5 + i_6 + i_7)$. In order to synchronize the voltage program with the circuit the switches k_1, k_2 k_3 must be switched off when the current transfer reaches zero, the required voltage being maintained by the connection of the appropriate switch (k_4 in Fig 2). This lay-out allows for a very accurate system, which

Card 1/4

The Programming of Welding Processes

is also synchronized with the circuit, and can in addition be used for programming other factors, such as pressure. In this case peak-transformers (Fig 2) or rapid-action electromagnetic relays are inserted in the circuit; the peak-transformers have 2 peak windings, each feeding its own group of tiratron circuits (even and odd). This voltage cycle must be repeated periodically for the programming of roller welding, all the tiratrons being switched off in the same way as above by means of a discharge circuit (Fig 3). Fig 4 contains an oscillogram of the program voltage illustrated in Figs 2 and 3. In the section devoted to welding processes of average duration, the author deals with operations lasting 1-2 secs. These can be carried out in accordance with the aforementioned method, but to avoid an excess of switches, an auxiliary electro-mechanical apparatus is installed, which guarantees the regular discharge of impulses. This consists of a peak-transformer in which voltage peaks are formed at moments of sharp alteration in the magnetic current, caused by the proximity of a

The Programming of Welding Processes

steel disc, which is synchronized with the circuit (illustrated in Fig 5a); the voltage peaks are illustrated in Fig 5b. Since one path of movement for the steel discs is insufficient, several are used, the number of peak-transformers equalling the number of paths. Finally, the programming of prolonged welding processes is dealt with. Here there is no need for synchronization with circuit voltage or for maintaining program voltage during each half-period or period; a programming installation for this kind of welding process must be of constant voltage, alternating at fixed intervals, it must be simple to use and must have no moving contacts. Photoelectric installations are the best for the purpose, and the program can be carried out as a black-and-white film (Fig 6a). Changes in the proportions of black and white are reflected in the amount of photoresistance and Fig 6b shows the dependence of the voltage at the bridge exit on the amount of light. This system can be used for several programs by means of a revolving

The Programming of Welding Processes

drum and the appropriate films; its advantages are its simplicity, its diversity of application and its clarity, while it is marred by being somewhat inaccurate. The inductive feeder shown in Fig 7 is sometimes used instead, enabling the sensitivity to be raised and zero discharge voltage to be attained. There are 7 diagrams and 2 Soviet references.

AUTHORS: Paton, B.Ye., Gavrish, V.S., Grodetskiy, Yu.S.

TITLE: Universal Welding Programmer

PERIODICAL: Avtomaticheskaya svarka, no.7, 1961, 15-20

TEXT: The Ordena Trudovogo Krasnogo Znameni Institut elektrosvarki im. Ye.O. Patona AN SSSR (Electric Welding Institute "Order of the Red Banner of Labor" im. Ye.O.Paton AS UkrSSR) has developed a new universal programming system called УПУ (UPU) for resistance welding machines. It eliminates the deficiencies of previously described programmers (Ref.2: B.Ye. Paton, Yu.S.Grodetskiy, "Avtom.svarka", no.10, 1959; Ref.3: V.N.Nikulin, V.I.Skurikhin, "Avtom.svarka", no.10, 1960) that were complicated and had no dependable program carrier. The UPU is a discrete system with a numerical binary code by which any number can be presented as a sum

$$N = \sum_{k=0}^{k=n-1} a_k 2^k,$$

where a_k can only have one of two meanings - 0 or 1. An example: the

Card 1/6

Universal Welding Programmer

number 53= $1 \cdot 2^5 + 1 \cdot 2^4 + 0 \cdot 2^3 + 1 \cdot 2^2 + 0 \cdot 2^1 + 1 \cdot 2^0$ = 110 101, i.e. 53 will be represented by six digits on the program carrier. The system is illustrated in a block diagram (Fig.1) where the program carrier in the input bloc (ВП) is a punched disc (Fig.2,b). It is driven by a synchronous motor, and the program can easily be synchronised with the network voltage and repeated. The photoelectric information reader unit (СП, Fig.1) cannot cause disc wear. The third link of the UPU is the decoder (Д). The reading head is placed above the rotating punched disc and consists of a set of air-cooled germanium phototriodes, 6.3 v, 0.28 amp light bulbs, and an orifice plate with slits. The perforations in the disc give the program of welding current and pressure; 4-5 rows of perforations are sufficient for current, 1-2 for pressure, and one for start synchronization. Programs can be prepared at industrial plants without complex computing devices. Tables must be prepared by production engineers, and then the discs punched according to the table data in a puncher consisting of two discs with drilled holes. A black paper sheet is put between the discs and punched. The presence of a hole in the carrier means 1, the absence of a hole - 0. Light passing through perforations and falling on a phototriode produces voltage pulses in an electrical circuit. These pulses are fed through an amplifier unit into

Card 2/6

Universal Welding Programmer

the decoder, at whose output a stepped program voltage (Fig.3) is obtained. This voltage can easily be converted by phase shifters into the phase of the ignition angle of thyratrons in the power circuit. The decoder (Fig.4) consists of a row of trigger cells (T_1, T_2, ..., T_m) with thyratrons passing a current flow $I_{o.fl}=1 \cdot 2^n$ current through the resistor R_m. The exponent n is different for each cell and is determined by the formula

$$n = k \frac{U_n}{R_m + R_{thyr}},$$

where U_n is the trigger feed voltage, R_m - resistance in the cathode, R_{thyr} - the thyratron resistance, k - the proportionality factor. The exponent n can be chosen by selecting resistances R_m to pass current I_{fl}, $2I_{fl}$, $4I_{fl}$, $8I_{fl}$, etc. The current through the common resistor (R_o) will be:

Card 3/6

Universal Welding Programmer

This resistor adds the trigger cells current, and the voltage drop in it (stepped) is the output of the whole programmer. The punched disc is driven by a synchronous motor, and the phototriode pulses and the output voltage are synchronized accurately with the network, which is important for operation with ignitron interrupters. Multiple repetition of the program for seam welding is possible. A special trigger cell is controlled by a voltage pulse from the start holes on the punched disc and makes it possible to start welding only at a definite moment, regardless of when the operator steps on the control pedal. Pressure on the electrodes in spot welding can be varied by a program recorded on the same program disc. The described universal programmer can work with thyratrons in trigger cells, or with transistors. Conclusions: (1) The developed programmer permits any desired variations of current and pressure; (2) The computing techniques ensure high interference-killing capacity and dependability of the system; (3) Punched program discs may be produced at a center and supplied to the plant; this will result in strict technological discipline, higher precision and stability of program

TITLE: Decatron programmer

PERIODICAL: Avtomaticheskaya svarka, no. 5, 1962, 1-4

TEXT: The programming system for spot and seam resistance welding is an improved version of a universal programmer, previously described by the authors ("Avtomaticheskaya svarka", no. 7, 1961), which had a punched disc, mechanical elements for inserting the program, too many electron tubes and thyratrons, and did not permit immediate repetition of the program. The program carrier in the new system is an immobile punched card, the reader arrangement a set of contacts connecting through the card holes. A -101 (A-101) commutating decatrons accurately scan the program in step with the supply network voltage. The maximum cycle time depends on the number of decatrons used. The decoder comprises a series of transistorized amplifier-limiters, the current from which passes one resistor; the output voltage from the resistor controls the phase shifter. The

Card 1/2

start circuit includes blockings and auxiliary units, and is switchable for spot or seam welding. Programming calculations using tables ("Avtomaticheskaya svarka", no. 7, 1961) are not time-consuming and require no computers. A detailed description of the decatron programmer design and operation principles is given. There are 4 figures.

TITLE: Electronic (inertialess) schemes for automatic control of resistance-welding processes [Report at the Conference on Automatic Welding Control, Kiev, 25 December 1962]

SOURCE: Avtomaticheskaya svarka, no. 5, 1963, 7-10

TOPIC TAGS: electronic welding controller, resistance welding

ABSTRACT: Some well-known ways for attaining a higher speed of welding control are considered. A new welding controller designed on the principle of quenching the ignitrons permits practically inertialess controlling of the welding process. The quenching occurs at the moment when the welding current (or voltage) is equal to the set current (or voltage). The controller is suitable for applications (e.g., radio-tube industry) where the welding-current duration is 0.02-0.01 sec. The controller block diagram is shown in Fig. 2 (see Enclosure 1). With the controller on and a supply voltage of 190 v, the strength of test-welded specimens was 3-5 per cent lower than that at the rated 220 v. Other things being equal, with the controller off, the strength reduction was 30-40 per cent. Orig. art. has: 1 formula and 4 figures.
